The Dynamics of Value across Global Equity Markets:
The Risk Contagion

June 24, 2015
Motivation

Valuation Metrics
- Price-Earnings (P/E), Price-Book (P/B), Price-Earnings to Growth (PEG) Ratio
- Debt/Equity Ratio
- Free Cash Flow

Piotroski Score (2000) point based score between 0-9
- Profitability (0-4)
- Leverage, Liquidity and Source of Funds (0-3)
- Operating Efficiency (0-2)
Stock Market Valuation

- Lakonishok et al. (1994); Chan & Lakonishok (2004)
- Van der Hart et al. (2003)
- Bakshi & Chen (2005)
- Bartov & Bodnar (1994); Frankel & Lee (1998)
Cross sectional aspects of dynamics of valuation metrics across global equity markets.

The periods when markets are driven by euphoria and fear.
Computing CAPE

- CAPE is defined for a stock market index $I$ at time $t$ as

$$CAPE_{M;t}^I = \frac{rP_t^I}{Avg_{M;t} \left[ rEPS_t^I \right]},$$

where the numerator, $rP_t^I$, is the price level of the index $I$ at time $t$ expressed in real terms as

$$rP_t^I = P_t^I \cdot \frac{CPI_T^I}{CPI_t^I},$$

where $CPI_t^I$ is the last published consumer price index at the domestic country to index $I$ at time $t$, $T$ is the reference date taken as the last time in the sample and $P_t^I$ is the price level of the index, and the denominator $Avg_{M;t} \left[ rEPS_t^I \right]$, is the average of the earnings per share, expressed in real terms, over a past window $M$.\(^1\)

\(^1\)\(EPS_t^I\) is published as 12-month trailing average.
We assume that $Avg_{M;t} \left[ rEPS^I_{t'} \right] > 0$. As $Avg_{M;t} \left[ rEPS^I_{t'} \right] \to 0^+$, the CAPE is diverging, where for negative average earnings, the CAPE is negative as well.

We consider only those indices, for which $Avg_{M;t} \left[ rEPS^I_{t'} \right] > 0$ and thus CAPE is well defined.
Empirical Data

- We use 7 year moving average of inflation adjusted EPS to compute CAPE
- We have 34 equity markets for this study
- We use Weekly MSCI Index data starting from January 2002 till December 2014
- Our dataset has 21,216 observations
Market Index and MSCI Index Data

- Daily Return Scatter Plot India All Share & MSCI (1993-2013)
- Daily Return Scatter Plot Brazil All Share & MSCI (1999-2013)
- Daily Return Scatter Plot Shanghai All Share & MSCI (1999-2013)
- Daily Return Scatter Plot Russia All Share & MSCI (1997-2013)
### Market Clustering

\[ rt = \mu + \epsilon t \]  
\[ \epsilon t = \sigma tz t \]  
\[ \sigma_t^2 = \omega + (\alpha + \gamma I_{t-1}) \epsilon_{t-1}^2 + \beta \sigma_{t-1}^2 \]  
where
\[ I_{t-1} := \begin{cases} 
0 & \text{if } r_{t-1} \geq \mu \\
1 & \text{if } r_{t-1} < \mu 
\end{cases} \]  
However \( \omega, \alpha, \gamma, \beta > 0 \) (restrictions imposed) then the volatility can be modeled by the following expression,
\[ \sigma^2 := \text{Var}(r_t) = \frac{\omega}{1 - \alpha - \frac{\gamma}{2} - \beta} \]
Multivariate Asymmetric Dynamic Conditional Correlation Model (Cappiello et al. 2006)

\[ r_t | \zeta_{t-1} \sim \mathcal{N}(0, H_t) \]  \hspace{1cm} (6)

\[ H_t = D_t P_t D_t \]  \hspace{1cm} (7)

\[ Q_t = (1 - a - b)\bar{P} + a\varepsilon_{t-1}\varepsilon'_{t-1} + bQ_{t-1} \]  \hspace{1cm} (8)

\[ P_T = Q_t^{-1} Q_t Q_t^{-1} \]  \hspace{1cm} (9)
\begin{equation}
Q_t = (\overline{P} - A'\overline{P}A - B'\overline{P}B - G'\overline{N}G) + A'\varepsilon_{t-1}\varepsilon'_{t-1}A
\tag{10}
\end{equation}

\begin{equation}
+ G'n_{t-1}n'_{t-1}G + B'Q_{t-1}B
\tag{11}
\end{equation}

\begin{equation}
Q_t = (\overline{P} - a^2\overline{P} - b^2\overline{P} - g^2\overline{N}) + a^2\varepsilon_t\varepsilon'_{t-1} + g^2n_{t-1}n'_{t-1} + b^2Q_{t-1}
\tag{12}
\end{equation}

\begin{equation}
a^2 + b^2 + \delta g^2 < 1
\tag{13}
\end{equation}

where \( \delta = \text{maximum eigenvalue} \left[ \overline{P}^{-1/2}\overline{N}\overline{P}^{-1/2} \right] \) \tag{14}
Empirical and Dynamic Conditional Correlations Canada

Results

![Graph showing empirical and dynamic conditional correlations over time from 1/1/2002 to 1/1/2014.]
Empirical and Dynamic Conditional Correlations (America)

Note: The solid black and gray lines depict the dynamic and the static correlations between the $\text{CAP}_t$, $\text{H}_t^r$, respectively; the dash black and gray lines depict the dynamic and the static correlation between the price levels, $\text{H}_t^r$, respectively. The shaded region depicts the 95% confidence interval for the static correlation of the price levels, which serves as a benchmark.
Empirical and Dynamic Conditional Correlations (Europe)
Empirical and Dynamic Conditional Correlations South Korea
Empirical and Dynamic Conditional Correlations (Asia)

Note: The solid black and gray lines depict the dynamic and the static correlations between the $\text{CAP}E_{t|t-1}$, $\text{H}_{t|t-1}$, respectively; the dash black and gray lines depict the dynamic and the static correlation between the price levels, $\text{H}_{t}$, respectively. The shaded region depicts the 95% confidence interval for the static correlation of the price levels, which serves as a benchmark.
We define the value spread as the spread between the dynamic correlations of CAPE and Price Returns.

We further benchmark this spread with the spread obtained from empirical correlations between CAPE and Price Returns.

We further compute a 95% confidence bound along the empirical correlations.
Value Spread America

Note: The dash line depicts the value spread between the static correlations of the price-based and $CAPE_{x}$-based valuation measures, the shaded region corresponds to the 95% confidence interval of the static value spreads, and the dotted line corresponds to the dynamic value spreads $S_t$. 
Value Spread Europe
Value Spread Asia

Note: The dash line depicts the value spread between the static correlations of the price-based and $CAPE_{4p}$-based valuation measures, the shaded region corresponds to the 99% confidence interval of the static value spreads, and the dotted line corresponds to the dynamic value spreads $S_t$. 
Future Work - Portfolio Optimization

- We use the covariances obtained at time (t-1) from Price Index and CAPE returns at time (t) from the DCC model, for asset allocation.

- We carry out our asset allocation on a weekly rebalancing portfolio across the sample.

- We further extend this work by looking into Market Volume data and Foreign Exchange rates to understand the movement of Hot Money.
It does not appear possible to explain the boom in terms of fundamentals such as rents or construction costs. A psychological theory, that represents the boom as taking place of a feedback mechanism or social epidemic that encourages a view of housing as an important investment opportunity, fits the evidence better.

- Dr. Robert Shiller
